

HazardOS Admin Manual

For the people who configure HazardOS: business owners, office managers, and whoever ends up owning the system.

For day to day use (booking surveys, building estimates, running jobs), see the **HazardOS User Manual**. This manual covers setting the system up and keeping it healthy.

1. Roles and what each one can do

Seven roles, in descending order of access.

ROLE	INTENDED FOR
Platform Owner	HazardOS staff, across all customers
Platform Admin	HazardOS support staff
Tenant Owner	The business owner
Admin	Office manager, operations lead

Estimator	Sales and estimating
Technician	Field crew
Viewer	Read-only office staff, bookkeeping

What each role can reach

CAPABILITY	OWNER	ADMIN	ESTIMATOR	TECHNICIAN	VIEWER
See financial screens (estimates, invoices)	Yes	Yes	Yes	No	Read-only
Sales hub (commissions, approvals, win/loss)	Yes	Yes	No	No	No
Create and edit estimates and jobs	Yes	Yes	Yes	No	No
Record time, photos, materials, checklists	Yes	Yes	Yes	Yes	No
Approve timesheets	Yes	Yes	Yes	No	No
Create and approve change orders	Yes	Yes	Yes	No	No
See material cost	Yes	Yes	Yes	No	Yes
Team, billing, and settings	Yes	Yes	No	No	No

The money rule

Technicians see no financial information anywhere: not estimates, not invoices, not contract values, job costs, material costs, or margin. This was a specific business requirement and it's enforced in the database, not just by hiding menu items. A technician who types the URL of a financial screen is redirected.

Technicians *can* record materials used on a job, because that's field work. They enter what was used and the office adds the cost afterward.

If you need someone to see money, give them Estimator rather than working around the rule.

2. Your team

Settings → Team

Inviting someone

Send an invitation to their work email and pick their role. They set their own password from the emailed link, so you never handle their password. Invitations expire; resend if one goes stale.

Changing a role

Change it here. It takes effect on their next page load, and menus adjust immediately.

Think about role changes in terms of the money rule above. Promoting a technician to estimator gives them every financial screen in the system, so do it because they need to quote work, not as a general reward.

Removing someone

Removing access does not delete their history. Timesheets, jobs, estimates, and notes stay attributed to them, which is what you want for records.

Remove access the day someone leaves. It's the single highest-value security habit in the system.

3. Company, locations, and branding

Settings → **Company** holds your business details, which appear on customer documents.

Settings → **Locations** covers multi-branch operations. New records can inherit the creating user's default location, which keeps regional reporting honest without asking anyone to think about it.

Settings → **Branding** controls how your documents look to customers: logo and presentation on proposals and invoices. Worth doing properly. These documents are often the most polished thing a customer sees from you.

4. Pricing

Settings → Pricing

Five rate types feed estimate line items:

TYPE	COVERS
Labor rates	Crew day rates
Equipment rates	Negative air machines, scaffolding, and similar
Material costs	Consumables
Disposal fees	Landfill and manifest costs
Travel rates	Mileage and travel time

Estimators pick from these rather than typing numbers, which is what keeps quotes consistent between people.

Keeping rates current

Rates drift out of date quietly, and the first sign is usually a job with poor margin. Review them when disposal pricing changes, at least annually, and any time material variance on jobs starts trending against you.

Job **material variance** is the useful signal here: it compares what was estimated against what was actually used. Consistent overruns on one material usually mean the rate or the estimate template is wrong rather than that crews are careless.

Only admins and owners can change pricing. Everyone in the organization can read it, because estimators need it to quote.

5. Message templates

Settings → Message Templates

Two tabs, Email and SMS. The system ships six default templates: one email (job confirmation) and five SMS (appointment reminder a week out, appointment reminder day of, payment reminder before due, payment reminder due today, payment reminder overdue).

Defaults are marked as such. You can edit their wording freely, and your edits persist. Templates use `{{variable}}` placeholders that fill in from the job, customer, and appointment.

Write templates the way you'd actually speak to a customer. The defaults are a starting point, not house style.

6. SMS setup

Settings → SMS

Choosing a provider

HazardOS supports **Twilio** and **RingCentral**. Pick one under **Provider**; the credential fields change to match.

Choose RingCentral if you already run your phone system there and would rather not hold a second account. Choose Twilio otherwise.

Switching provider affects new messages only. Messages already sent keep their original provider in the delivery log.

Twilio

Enter Account SID, Auth Token, and Phone Number from the Twilio Console. The number must be SMS-capable and in E.164 format (`+15551234567`).

RingCentral

Create a REST app in the RingCentral Developer Console with SMS permission, then generate a JWT credential for the user whose number will send. Enter:

- **Client ID** and **Client Secret** from the app
- **JWT Credential** generated under Credentials

- **From Number** in E.164 format, which must be assigned to the JWT user and SMS-enabled on the RingCentral side
- **Server:** Production or Sandbox

Check the server setting first if authentication fails. Sandbox credentials against production fail with an error that reads like a bad JWT, and this is the most common setup mistake.

Current RingCentral limitations

Sending and logging work. Two things do not, and both need RingCentral's subscription API:

- **Delivery confirmation.** A RingCentral message logs as sent when RingCentral accepts it, and won't progress to delivered the way a Twilio message does.
- **Inbound messages.** Customer replies are not captured, which includes STOP replies. If you run on RingCentral, you must handle opt-out requests manually until this is built.

That second point is a compliance matter, not a convenience one. Raise it before going live on RingCentral at volume.

Quiet hours

Set a window outside which no messages send. Appointment reminders that would land at 6am are the main thing this prevents.

Brand prefix

An optional short label prepended in square brackets, so customers know who is texting them.

Opt-out handling

On Twilio this is automatic and not optional. STOP, UNSUBSCRIBE, CANCEL, END, and QUIT opt a customer out of everything, including transactional messages like appointment reminders. START, SUBSCRIBE, YES, and UNSTOP opt them back in.

Do not attempt to work around an opt-out. It's a legal obligation, and the system will not send regardless.

Testing

Send Test SMS sends a single message to a number you choose to confirm credentials work. Use it after any credential change.

7. Email setup

Settings → **Email** configures the address customer email is sent from, and sender verification. Proposals, invoices, and feedback requests all go out this way.

Get the sending domain properly verified. Unverified senders land in junk mail, and the symptom customers report is "we never got your proposal".

8. Activity vocabulary

Settings → Activity Vocabulary

Two tabs:

- **Activity Types:** the kinds of work your team logs (initial contact, confirm appointment, send estimate, chase payment, and so on)
- **Outcomes:** how an activity ended (completed, left message, no answer)

Rename these to match how your business actually talks. The vocabulary drives automations, so the names matter beyond labeling.

Rows in use cannot be deleted. If an automation references an activity type, deleting it is refused and the message names the blocking chain, so you know what to change first. Deactivate rather than delete when retiring something that has history.

9. Automations

Settings → Automations

Automations are chains of steps that fire on an event: an opportunity reaching a stage, a job status changing, a lab result arriving, a message failing to send.

Each step has a kind, an assignee (a named person, unassigned for a queue, or whoever completed the triggering step), and a due date relative to when the chain fires.

Weekends

Each chain has **use Saturdays** and **use Sundays** settings, off by default. A due date landing on a day the office is closed pushes work into a day nobody works, and follow-up cadence drifts as a result. Leave them off unless you genuinely work weekends.

Building chains

Start smaller than you think you need. A three-step chain everyone follows beats a twelve-step chain people work around. Add steps once the simple version is running.

10. Credentials

Settings → Credentials

Track crew certifications and expiry dates. **Credential assignment enforcement** is set per organization and controls what happens when you assign someone whose certification has lapsed: warn, or block outright.

Blocking is stricter and occasionally inconvenient. It's also the setting that stops an uncertified technician reaching a regulated site, which is the more expensive problem.

11. Notifications

Settings → **Notifications** controls what the system tells people about, in-app and by email. Individuals can also set their own preferences under their profile.

Turn off what nobody reads. Notification fatigue is real, and a team that ignores every notification will ignore the important one too.

12. Integrations

Settings → **Integrations**

QuickBooks syncs customers and invoices. Connect through the OAuth flow.

Note: if QuickBooks credentials aren't configured on the server, the Connect button will send you to Intuit and fail there rather than telling you here. If Connect behaves oddly, check with your HazardOS contact that the integration is configured before troubleshooting your QuickBooks account.

13. AI features

Settings → **AI & Automation**

Three optional features: estimate suggestions, photo hazard analysis, and voice transcription cleanup.

They're off until you turn them on, deliberately. They involve sending job information to a third-party model, so they're gated behind explicit consent rather than enabled by default. The settings record who granted consent and when.

Related controls:

- **Retain AI data:** whether inputs are kept
- **Anonymize customer data:** strips identifying details before sending
- **Allow model improvement:** off by default

Turn on only what earns its place. Estimate suggestions help most on unusual scopes; on routine work your own templates are faster and better.

14. API keys and webhooks

Settings → **API** issues keys for the public API, with scoped permissions. **Settings** → **Webhooks** registers URLs the system calls when events occur.

Two habits worth keeping: give each integration its own key so you can revoke one without breaking the others, and revoke keys when the integration that used them is retired.

Settings → **API Docs** documents the available endpoints.

15. Billing

Settings → **Billing** holds your subscription, plan, and invoices from HazardOS. Owner and admin only.

16. Security

Settings → **Security** covers organization-level security settings.

What matters most

Remove people the day they leave. More important than every other setting here combined.

Give the least role that does the job. Estimator is not a courtesy title; it opens every financial screen in the system.

Rotate API keys when someone with access to them leaves.

Review the team list quarterly. People accumulate. Check the list matches who actually works here and that roles still match responsibilities.

17. Things worth checking monthly

A short list that catches most problems before customers do.

Delivery log. Are messages arriving? A rising failure rate usually means bad phone numbers or a provider issue, and it's invisible unless you look.

Pricing. Have disposal or material costs moved since you last updated rates?

Material variance on recent jobs. Consistent overruns point at estimate templates rather than crews.

Credential expiry. Anyone lapsing in the next sixty days.

Team list. Does it match who works here?

Unsubmitted and unapproved timesheets. Old submitted entries mean somebody isn't approving, and payroll finds out later.

Estimates sent but never opened. The estimate record shows first-view time. Never opened usually means the email didn't arrive.

Getting help

Your HazardOS contact can help with anything configured above the organization level: platform settings, integration credentials, and environment configuration. When reporting a problem, include what you expected, what happened, the affected record, and roughly when. That's usually enough to diagnose without a call.
